TC7MBL3245CFK

1. Functional Description

- Low-Voltage, Low-Capacitance Octal Bus Switch

2. General

The TC7MBL3245CFK is a Low Voltage/Low Capacitance CMOS 8bit Bus Switch. The low on-resistance of the switch allows connections to be made with minimal propagation delay time.

The TC7MBL3245CFK requires the output enable ($\overline{OE}$) input to be set high to place the output into the high impedance.

All inputs are equipped with protection circuits against static discharge.

9. Absolute Maximum Ratings (Note)

Characteristics	Symbol	Note	Test Condition	Rating	Unit
Supply voltage	V_{CC}			-0.5 to 4.6	V
Input voltage ($\overline{OE}$)	V_{IN}			-0.5 to 4.6	V
Switch I/O voltage	V_S		V_{CC} = 0 V or Switch = Off	-0.5 to 4.6	V
			Switch = On	-0.5 to V_{CC} +0.5

Note: Exceeding any of the absolute maximum ratings, even briefly, lead to deterioration in IC performance or even destruction.
Using continuously under heavy loads (e.g. the application of high temperature/current/voltage and the significant change in temperature, etc.) may cause this product to decrease in the reliability significantly even if the operating conditions (i.e. operating temperature/current/voltage, etc.) are within the absolute maximum ratings and the operating ranges.
Please design the appropriate reliability upon reviewing the Toshiba Semiconductor Reliability Handbook (“Handling Precautions”/“Derating Concept and Methods”) and individual reliability data (i.e. reliability test report and estimated failure rate, etc).

12. Rise and Fall Time (t_r/t_f)

The $t_{r(out)}$ and $t_{f(out)}$ values of the output signals are affected by the CR time constant of the input, which consists of the switch terminal capacitance ($C_{I/O}$) and the on-resistance (R_{ON}) of the input.

In practice, the $t_{r(out)}$ and $t_{f(out)}$ values are also affected by the circuit's capacitance and resistance components other than those of the TC7MBL3245CFK.

The $t_{r(out)}/t_{f(out)}$ values can be approximated as follows. (Figure 12.1, Table 12.1 shows the test circuit.)

$t_{r(out)}/t_{f(out)}$ (approx) = - $(C_{I/O} + C_L)$ · $(R_{DRIVE} + R_{ON})$ · ln $(((V_{OH} - V_{OL}) - V_M) / (V_{OH} - V_{OL}))$

Where, R_{DRIVE} is the output impedance of the previous-stage circuit.

Calculation example:

$t_{r(out)}$ (approx) = - (7.5 + 15) E - 12 · (120 + 6.5) · ln (((3.0 - 0) - 1.5) / (3.0 - 0)) ≈ 2.0 ns

Calculation conditions:

V_{CC} = 3.0 V, C_L = 15 pF, R_{DRIVE} = 120 Ω (output impedance of the previous IC), V_M = 1.5 V (V_{CC}/2)

Output of the previous IC = digital (i.e., high-level voltage = V_{CC}, low-level voltage = GND)
